## Manual-overview of system

## 1. iAStar AS380

## Characteristic

- Converter and control in one unit
- Reduced wiring
- simplified parametrisation and commissioning
- 32bit processor ARM7 industry standard
- Dual processor design for enhanced safety requirement
- 2x CAN interfaces for internal \& external communication
- High EMc-stability (EFT-4000V)
- High ESD-stability (ESD 8000 V )
- EN81, GB7588, CE certified

## scope of operation

- For synchronous and asynchronous drive
- numerous parameterizable operations for almost all types of lifts.
- Lifts from $0,1 \mathrm{~m} / \mathrm{s}$ to $10 \mathrm{~m} / \mathrm{s}$.
- Up to 64 stops
- 2 group cluster integrated
- up to 8 in one group with group controller
- prepared for call control
- shaft copying by shaft encoder and magnetic sensor
- compensation of load during start with and without load measuring unit

- ID-card system( id card-transponder) integrable
- remote monitoring local and global
- 7 segment disply on board
- graphic LCD on separated handtool
- depiction of driving cycle, input \& output state,statusinformation
- error memory ( 20 errors) with real time registration plain text display.
- Standard for two cabindoors
- numerous special functions eg automatic evacuation .with load dependant selection of direction

## Manual-overview of system

## 2.Overview of system

SmartCom is a modern, on newest technology based control system especially for elevators.
The system consists basicly on compnents as follows:

- Control circuit terminal iAStar AS380 with integrated frequency converter
- car controller panel SM02G
- command board SM03 panel for keys
- Car top control board SM02H
- Display\& control board SM04
- Extension board SM09

Different variations from each of the the panels/ boards enables an otimal match between the control system and the elevator in the required range.
Simple or complex controls based on the always consistent CANrecords could be implemented.
All components are combinable and extensible due to the CANsystem.

## Integrated frequency converter iAStar AS380

This modul optionally in the shaft or outside consists of the frequency converter and the central unit SM01 of the elevator control. It includes all functions, especially the drive control, detection of carposition and a lot of special functions, which are normally allocated in the shaft or engine room. It communicates via the CAN-Bus with the other modules.

## Car controller panel SM02

All functions which are related to the cabin are realised by the car controller panel. It is connected via CAN-bus with the control circuit terminal.
There are two variations. The „classic" which only one SM02/03, and now with the 32bit board F5021 established fragmented variation. In this case there is integrated one SM02/H in car top control panel and one SM02/G the car controller panel. Thus the 36 -pole cable is reduced to a 12 pole control casble between the car top panel and the car controller panel. The connection from up to three additional car controller panels/ console panel is now very easy via CAN-bus.

## Command board panel SM03

This board is connected to the car controller panel. Up to 8 panels can be connected to an SM02. One command board provides 8 inputs \& 8 outputs for the related confirmations.

## Display \& control board SM04

Those boards could somehow used as floor-display in the cabin or other as floor display for each floor with indication of floornumber and continuing indicator.

## Manual - overview of system

The adressing is made by DIL-switch or the floor button.
The SM04 is available in different designs: Horizontally, vertically and vertically-slim. The diplays varies in design and circumference and can also be customized.
All SM04 can communiucate via CAN-bus and are combinable in any order.
In the floors on the SM04 Modulen (Disply+CAN-Modul) the push-buttons for the hallway calls and the key-switch for special function. Newer panels permit also to connect a loudspeaker for the EN81-70 required beep.

## Special board SM09

Via those customized special functions could be realised without changing the control circuit. For example the electronic electronic custodian system of the customer or additional fault-messages.

## Functional overview

| Standardfunctions |  |  |
| :--- | :--- | :--- |
| 1 | Group controllers | Collecting hall calls with respect to the given direction |
| 2 | Inspection run | Up or down. In the door zones the door open button can be used to open <br> the door. |
| 3 | Self liberation with slow drive | If you miss the door zone in normal mode the elevator drives slowly with <br> closed door into the levelling position and opens the door. |
| 4 | Testrun | For Testpurposes the elevator can make a determined number of random <br> testruns |
| 5 | Realtimeclock | Errors are registrated with date and time. Functions can be temporary <br> activated |
| 6 | Time to keep doors open | Dependant of the kind of call ( Interior, exterior, service, special call), <br> the time to keep the doors open can be indicated. |
| 7 | Door opening by local calls | Is the elevator allready in the floor from which the call comes, the door <br> opens. |
| 8 | Premature closing of the door. | With the door close button the door can be closed before the „Door <br> open-Time". |
| 9 | Forced opening of doors | Inside the the door area with the door open button the door opening can <br> be forced for closed doors which are actually closed. |
| 10 | Return motion automatic | In case the cabin is not closed within 15 sec. after arrival at the door- <br> close endswitch, the door open again for a new try. |
| 11 | Monitoring of door opening | If 15 sec. After opening of the door the final door switch is not the door <br> closes for a new try. |
| 12 | Cancelling of call | Via double -CLICK of a call button the call can be cancelled. |
| 13 | Terminal landings | In the upper terminal the UP command is deleted; in the lower terminal <br> the down command is deleted. |
| 14 | Direct drive | Direct drive without rat run. Is activated when incremental copying and <br> analogue control. The travel curve at this will be created by the <br> controller, |
| 15 | Cabin Full | If full load, the cabinet do not stop anymore for hall calls |
| 16 | Cabin door light OFF | After 5 Minutes without activity the cabin light is switched OFF |
| 17 | Parking drive | After a ajustable time without activity the elevator drives into main floor |
| 18 | LCD control | Graphic display with extensive status information and menu navigation |
| 19 | The rotation frequency of frequency converter is guided by the analogue <br> output. |  |
| 20 | Digital speed inputs setting. | Optional the speed can be set via contacts. |

Seite 4

## Manual-overview of system

## Manual - overview of system

|  |  | office building) |
| :---: | :---: | :---: |
| 11 | Rush hour emptying building | Via internal time settings the haul capacity can be adapted ( typically office building) |
| 12 | Dispatch waiting elevator | When all calls are executed after 1 min the elevators of a group are distributed in the building; one is going to the main parking floor the others remaining in different parking positions to reduce waiting time. |
| 13 | Interface to building control system | RS485 interface to link to PC for building control |
|  | Remote monitoring | The elevator can be integrated in an overall remote monitoring system. |
| 15 | Drive in Gong | During the landing approach a gong under the floor or over the ceiling of the cabin informs about the arriving cabin. |
| 16 | Driving on displays HOP | In the hall indicator panels with an accoustic and optical display could be integrated. |
|  | Floor gong | In every floor a Gong could be provided. |
| 18 | Card reader in the cabin | With a transponder card could either a specific call be released or presetted calls be released |
| 19 | Card reader in the floors | Release of hall calls |
| 20 | Selective door control | Back-and frontdoor could be separated. |
| 21 | Push mode | After 1 min the door is closing slowly despite the light array. |
| 22 | VIP Service | A key switch in the HOP deletes all hall calls and brings the empty cabine. Now several inside calls could be setted. After this the elevator switches back in normal mode. |
| 23 | PIN entry via call button | For specific selection of floors the call buttons can be used to entry a PIN |
| 24 | Floor activation locally controlled | For simple or duplex elevators an altered setting of floors can be entered via key switch. |
| 25 | Floor activation via group control | Floor settings can be temporarily changed via groupannexe |
|  | Temporarily blockade from individual floors | Floors could be blocked for short time from the user. |
| 27 | Automatic Evacuation | In case of a power failure with following emergency power supply the cabin runs to the next floor |
| 8 | Emergency power evacuation | For elevator groups the evacuation is made one after another. |
| 9 | Earth quake Function | Elevator stops during run and brought to the evacuation stop. |
| 30 | announcement | Serial and parallel connection for announcements |

## Manual-overview of system

3. Hand device

| ESC | Parameter/leave menu |  | ENTER | Select parameter, <br> set parameter/take over param. |
| :--- | :--- | :--- | :--- | :--- |
| F1 \& F2 | Quick select from error storage, In-Out <br> display-, CAN- and shaft encoder |  | F3 | Quick select graphic drive curb |
| $\square$ | Next Parameter/menupoint <br> Increase of choosen decimalplace |  | Jump back 10 parameters/ <br> one decimal point left |  |
| $\square$ | previous Parameter/Menupoint <br> Decrease of choosen decimal point | $\square$ | Jump forward 10 parameter <br> one decimal point right. |  |

## Manual - overview of system

## operation:

In normal case the state, the group affiliation, actual floor, actual speed and the actual state of doors or drive

The number in the $2^{\text {nd }}$ line depicts the counter of runs can also be setted for another value.

## Log in:

To see the state or to set parameter you have first to login. After pushing the ENTER button appears the password. Standard for the Password „1234". After login under Chg.Password" the password could be changed.. Attention! Don't forget Password! The control can be unlocked only in the fatcory without Password!

## Menu

The complete menu tree you'll find under „, Menu tree \& parameter.
The Startwindow shows state, group affiliation, actual floor, actual speed and the actual state of doors or drive.

With „Enter" you're going to main menu. Again Enter select Monitor-Menu, which has all diagnosis windows.

Startwindow

Login

## State menu under „Monitor"

Run State conforming to the start
In the first line you see mode (Normal, Inspection, Fire Return, Firemen, Park) and state of group (Simplex, Group).
Below counter of runs, Floor, speed and the actual action.

In Call. Func. The actual calls are depicted and you can also set calls (with the arrow up/ dwn and Enter).
Cabin calls, hall calls up and down.

Speed Curve is the graphic depiction from speed encoder. Above the actual speed and running time is indicated.

In the window Input\&Output all inputs and outputs are depicted.
With the up/dwn buttons youre switching between the 16er groups.
With right/left a single input/ outout could be marked. In the line below appears the function of this input/ output.
The designation X (Input SM01) and Y (Output SM01), plus TX (Input SM02) and TY (Output SM02) you'll find in the electrical circuit.

## Manual-overview of system

In the fault Record the last 20 faults are depicted with date, time and which floor.
The newest fault ist always shown at first.
With UP/ down you're moving between the entries in the list. With ENTER a new window appears with date, time and clear text entries.

The list Shaft Data includes the floor positions which had been determined during the learning movement in mm. By this you can easily check wether the positions had been correctly detected during the learning movement.

The windows Encoder Eva und Communication are helpful when problems with the encoder or CAN-bus occurs.

In the version window date and version number of the firmware are shown. Before updating you should check wether the update is more actual then the existing one.

## To set parameter in the submenu Para.Select

Via the parameter menu you can acceed on numerous parameters. There are groups of parameters where the parameters are thematically arranged. For example motor or door parameters. There is also a list where parameters are asorted though numbers.

```
Para. Select
================
->Main Para.
Insp. Option
```

Most of parameters could only be set in inspection -or return motion mode. If the warning appears switch to inspection mode.

All parameter are set in 16bit integer numbers. Most of them in decimal numbers together with the unit.
Eg 50 with a setting of $0,1 \mathrm{~s}$ means 5 seconds.

Some of the parameters only exist as a bitmask. Depicted is a decimal value, but as soon you want to set a value the bitmask appears and with left/ right you can move and set or delete the values.
(* means set, - deleted).
In the lower line appears the description of the Bits.
By this for every input the logic break/ make contact could be individually set.

## Manual - overview of system

Insp.Option include all parameters which are necessary for the start-up in the inspection mode
S Curve is needed for the use of the analogue Output of the converter control.

Lvl.Mic.Adj. Enables the correction of each levelling at every floor.
Normally not necessary because the floors are calibrated during the learning movement.

Multi Speed includes all parameter, which are necessary for the run of the converter in multistep-mode ( parallel control).
Door Control enables the parametrisation for door control.

Flr.Disp. Leads to the list of the floor idicators.
For every floor you can set individually the displayed letter combination (for Step SM04 displays). The announcement for the landings on each floor is fixed by this dsiplay code.
The Display codes are stated in a chart in the appendix.
Service Floor determines the enabled floors. Also the floors which are only enabled by key-switch are determinded.

Block Floor permits blocking of a floor via time or key switch..

Comp. Stop (enforced stop) defines stops where the elevator is brought to an enforced stop when passing by. Make sense in some cases for Hotels.
Heavy Traf. Permits the function „emptying/ filling building".
So the haul capacity of a office building could be increased

In Test Run the parameter F34 can be set for a number of runs, which the elevator should make without any command for testing purpose.
Para. Setup is the access to the complete parameterlist.

Reset brings all parameters to factory setting. Has only be made if absolutely neccessary! Before the Reset a number has to be entered to avoid an accidantly reset.
Attention! After the entry of the number the reset is made without any further inquiry!
Set F146 imperativly on 0 !

```
Para. Select
===============
>Insp. Option
    S Curve
```

| Para. Sele |  |
| :---: | :---: |
| ->Lul. Mic. Hulti Spe | Lul. Micro Adj |
|  |  |
|  | Flr. Lul.ll Adj |

Para. Select

>Flr* Disp.
Seruice Flr
```

```
Para. Select
==============
->Seruice Flr".
Block Flr.
```

```
Para. Select
===============
>Comp = Stop
Heauy Traf.
```

```
Para. Select
==============
>Test Run
Para. Setup
```

## Manual-overview of system

## different functions (Func.Select)

Time Setup: setting of then realtime-clock. Is needed for the fault-record and the time dependant enabled floors. And also for the function „filling/ emptying building".

```
Func. Select
===============
>Door" Teach
Shaft Teach
```

Shaft Teach: has to made imperativly before going to normal mode ( after mounting or changing door position)
Door, bus, shaft copying and cabinlight has to work correctly.
After activating of shaft teaching the elevator runs in the lowest stop and starts with the learning movement.

```
Func. Select
================
->Shaft Teach
Reset Para.F
```

After finish the elevator can go into normal mode. If an error occurs the learning movement is stopped and an error messages appears..

Reset Para.F: Rest on factory setting!!!
Reset Errco.: deleting of fault record!

Error Reset: Reset after Lift Error (fatal fault) eg. Run monitor, contactor monitoring, Bakemonitoring etc..
Relogin: Logout and relogin.
Normaly after 10 min . without input automatically logout!
Chg.Password: changing Password
Attention! Don't forget password-could only be resetted in factory!

## Manual-overview of system

| Function | main | sub | description |

## 5. Commissioning -Installation run

Attention! Before start for the first time, check wether CAN-Bus is inactive ! Means that JP4 on the circuit AS380 terminal is disconnected!<br>By this blocking from HDR Lock Error (Steuerung had detected bypassed security loop)is avoided. Is blocking already active see HDR Lock Error.

## General:

Installation and commissioning should only be made from personel which is familiar with the electrical and mechanical mannerism of the elevator. Deficient commissioning or installation can provoque risk for life and limb.Due to the characteristes bypasses have to be made during installation. Most of the bypasses are already set for testing reasons on the test facility.
During the installation process those bypasses are removed and replaced by security switches.
As soon as a new component is mounted eg folding support, loop into the security circuit!

On sheet 3 of the wiring diagram the complete security plan is depicted.
Check all security switches on their correct function and effectiveness.
Especially the switches on the fold -away-bracket in the security space and the folding support.
At X88 on Servicepanel measurement in the security loop could be executed.

## Condition for commissioning run:

- Drive, Control cabinet, service panel and brake resistance are mounted and connected. (don't forget Temperature monitoring at X4.3 and X4.4 eventually bypass otherwise K0 doesn't actuate.
- Car top control is fixed and connected via the trailing cable. If not so, provide bypasses (sheet 3 ) and switch S50 on Inspektion.
- Sheelds from motor, brake resistance and encoder are correctly placed.
- Security loop is closed up to X20 (display on inverter LED board or on Service Tool in Monitor/Input-Output X20 und X21).
- Check parameter on Servicetool (see Details below)
- Now push Inspecion Auf or Ab , the Motorcontactors should actuate and the inverter should execute for $1^{\text {st }}$ time a tuning (Phasenwinkel). Identifiable by a noise. (If Contactors don't actuate, check wether security loop is closed while switch „Inspektion / Auf/ Ab" is pushed up to X21 -otherwise a bypass is missed or a switch is open-indication on service tool.
- Motor should slowly start after the „tuningnoise". If he is jumping, repeat tuning (for this set Parameter F242 at 0 and restart commissioning)
. If motor is still jumping, change two phases and repeat previous pace.

## Manual - overview of system

## Groupfunction

The parameters for the groupfunction has to be set as follows::

- $\quad$ F23 $=3$ (on each control, which is in a group)
- F181 = 0-7 (Number of elevator in one group-the lowest number has highest priority)

## Security loop - Return-motion -control

First ashure that security loop is closed
If it is necessary to bypass parts of securityloop, precautionary measures has to be taken for running the cabin.
One has to make shure that nobody is in the range of the doors or in the shaft!

At first connect all existant security switches and elements
If this is not possible the relevant strapping plugs should be placed.

## First movement with the Return-motion -control

When it is checked that there is no danger of collision first run with return-motion-control could be made.

If the elevator does not move in the intended direction, the correct rotation direction should only be set via the inverter.

Please go to following menu part
F - XXX
Parameter F234 $=0$ (change to 1 )
Parameter F234 = 1 (change to 0$)$

## Setting the parameters on AS.T030

Depiction 7-Segment Display on a AS.T030 board in normal operatin state

## Manual-overview of system

When pushing the arrow push-button left and right the menu points are depicted choose menu ,„LOGIN"‘.

Now the 4-digit password could be entered. By pushing the up/down arrow you set the number, by pushing left/right the ciphers are set. The cipher is blinking in a 1 sec pulse. Password: 1234

Push Enter

The authorization for changing password is now enabled.
When pushing left or right the parameter menu could be choosed.

## Manual - overview of system

In a 2-second pulse the value of choosen parameter is depicted.

When pushing up/ down button the individual parameters are selected. A change is enabled by pushing enter. Again enter confirms value.

## Checking parameters for commissioning and eventually adapt

Normaly the parameters are set in the factory at the test field.
Since there are three 3 makes and several power class used, it is possible that the pre-set values are inappropriate. Is there another drive than Sassi or Torin in use or the speed is other than $1 \mathrm{~m} / \mathrm{s}$ please imperativly check the parameters!

| Par. | name | Function | Setting | Remark |
| :--- | :--- | :--- | :--- | :--- |
| F06 | Speed | Rated speed | $1,0 \mathrm{~m} / \mathrm{s}$ | Attention! If a motor asigned for 1m/s is <br> driven with 0,63m/s , rated frequency <br> (hz) and rated revolution (RPM) has to <br> be reduced correspondantely! |
| F12 | Insp. speed. | inspectionspeed | $0,25 \mathrm{~m} / \mathrm{s}$ |  |
| F16 | Braken open <br> redardation. | Retardation -Brakeopen | $0,2 \mathrm{~s}$ |  |
| F17 | FU enable. retardation | Time for brake come-in <br> compensate | $0,5 \mathrm{~s}$ | Could be considerably longer for Swiss <br> Traction |
| F25 | Input TypeX0-15 | Input logic (NO/NC) input |  | Normally presetted; for commissioning <br> the inputs of pre-endswitsch should be |
| F26 | Input TypeX16-25 | AS 380 main board |  | (X4,5,18 und 19) als NO (closing <br> contact,normally open) |
| F36 | Brake switch M. | Brake monitoring | 0 | Brake monitoring should be inactive as <br> long as brakeswitch is not connected. |

Seite 20

## Manual-overview of system

| Par. | name | Function | Setting | Remark |
| :---: | :---: | :---: | :---: | :---: |
| F59 | Retardation brake off | Stoptime during start | 0,5s | Came out as good compromise between slight Rollback and fast Start . |
| F62 | Running time limit. | Runningtime monitoring | 32s |  |
| F76 | Lim. UpDis. Ins. | End of insp. up | Omm | To avoid problems due to missing shaft copying set on „0". later there were adopted not to run up into pre-end switch Inspection and down not into support. |
| F77 | Lim. DnDis Ins. | End of insp. Down | 0mm |  |
| F122 | Retard. Run Insp | Retardation between Brake OFF and running signals | 0-1 s | Is only working when stopping by pushing Auf and Ab during inspektion |
| F165 | Door Kontr.Spez. | door open functionality | 0 |  |
| F175 | Start creep-speed | Creep-speed during Start | 0,006m/s |  |
| F180 | Analog value-> Vnen | Attribution speed to rated speed | 100,00\% | Shouldn't be changed |
| F186 | Duration of creep-speed when Start | Duration of creep-speed when Start | 0,5s |  |
| F201 | FU Modus | Inverter Modus | 3 | Vector Modus with encoder |
| F202 | Motort Type | Motor Type | 1 | Synchronous-Motor |
| F203 | M Rated Power | Rated motor power | 4kW | This are values for Torin at $630 \mathrm{~kg} / 1 \mathrm{~m} / \mathrm{s}$. At $0,63 \mathrm{~m} / \mathrm{s}$ result a frquency of $16,67 \mathrm{~Hz}$ at a revolution of 100RPM! In any doubt check type-plate. |
| F204 | M Rated Current | Rated motor current | 10,5A |  |
| F205 | M Rated Freq | Rated motor frequency | $26,25 \mathrm{~Hz}$ |  |
| F206 | M RPM | Rated motor revolution | 159RPM |  |
| F207 | M Rated Voltage | Rated motor tension | 380 V |  |
| F208 | M Pole Num. | Numper of poles | 20 |  |
| F209 | M Slip Freq |  | 1.4 Hz |  |
| F210 | Encoder Type | Type of encoder | 2 | EnDat |
| F211 | Encoder Pulses | Number of pulses encoder | 2048 |  |

F212 to F226 are for the revolution controller and so for die running quality. See also description „Parameter Drehzahlregler"

| F227 | Brake Time | Retard brake fall in | $0,2 \mathrm{~s}$ |  |
| :--- | :--- | :--- | :--- | :--- |
| F228 | Curr. Descent T | Time for demagetisation | $0,3 \mathrm{~s}$ | Should be ok to avoid „knack" after stop. |
| F232 | Encoder.Filter.Time | Time for filter <br> encodersignal | 1 ms | 1 ms proved as ideal. |
| F233 | Enc. Direction | Sense of rotation encoder | 1 | Has to be at 1 If OC Error or jumping <br> after tuning. Change motorphase! |
| F234 | Motor Phase | Adoption direc of rotation <br> motor | 1 | If Auf and Ab doesn't correspond with <br> direction of cabine-set on 0. |
| F239 | Output-Torq Lmt | torque limit | $175,00 \%$ | Could be raised ev. Up to 200\% |

## Manual - overview of system

| Par. | name | Function | Setting | Remark |
| :--- | :--- | :--- | :--- | :--- |
| F242 | Enc Phase Angle | Phase angle of encoder | $? ?$ | By setting on 0 the tunning could be <br> forced for next run. <br> If for every tuning the same value came <br> out-somethingn is wrong with encoder <br> cable orn bobine of motor. |
| F245 | Selection of F246-255 <br> Parameter Function | Choice of parameterfunction | 6 | The following parameter only have the <br> function if F245=6t! |
| F246 | Synchronous motor <br> study when power on | Automatic measurement <br> offsetangle after power <br> failure | 0 | Since a absolute encoder is used, the <br> offset angle has only be determined once <br> during mounting. |
| F247 | current gain when self <br> study | Measuring current for <br> offsetangle | $100,00 \%$ | Standard is $150 \%$, but is has proved that <br> $100 \%$ is a better value for tuning and <br> noise is reduced. |

## Parameter speed controller

The following parameter have influence during commissioning and for normnal run. In praxis the following parameters has proved workable especially for Torin motors. For SWISS-traction motor the values could be set considerably lower!.

| Nr. | Parameter | Funktion | Typ. | Hinweise |
| :--- | :--- | :--- | ---: | ---: |
| F212 | ASR P0 | P-Factor speed controller zero-rev. | 70 |  |
| F213 | ASR I0 | I-Faktor speed controller zero-rev. | 50 |  |
| F214 | ASR D0 | D-Faktor speed controller zero-rev. | 0.1 |  |
| F215 | ASR P1 | P-Faktor speed -controller for lower rev | 40 |  |
| F216 | ASR I1 | I-Faktor speed-controller for lower rev. | 5 |  |
| F217 | ASR D1 | D-Faktor speed-controller for lower rev. | 0.1 |  |
| F218 | ASR P2 | P-Faktor speed controller for middle rev | 60 |  |
| F219 | ASR I2 | I-Faktor speed controller for middle rev | 30 |  |
| F220 | ASR D2 | D-Faktor speed controller for middle rev | 0.1 |  |
| F221 | ASR P3 | P-Faktor speed controller for high rev. | 60 |  |
| F222 | ASR I3 | I-Faktor speed controller for high rev. | 4 |  |
| F223 | ASR D3 | D-Faktor speed controller for high rev. | 0.1 |  |
| F224 | Change Freq0 | Below this value PID1 is avive. Between <br> F0 and F1 PID2 is aktive | $1.0 \%$ |  |
| F225 | Change Freq1 | Above F1 PID3 is active | $50.0 \%$ |  |
| F226 | 0 Spd.Servo Time | Time during motor is hold on 0 revolution <br> when started. | 0.5 s |  |
| F227 | Brake Time | Time for revolution 0 when STOP | 0.2 s |  |

Seite 22

## Manual-overview of system

## HDR Lock Error

This error indicates that a securityloop is bypassed. The control detects that the door close switch reports"doors open" and the security-loop is closed.

This error blocks the elevator.To avoid this during installation you keep first the CAN Bus away. Door open end switsch is first reported from SM02/H in the inspectionbox.

To leave this condition the door-OPEN end switch has to be bypassed or the input logic has to be switched from NC to NO .

## Manual-overview of system

## 6.shaftcopying

The shaftcopying consist on an incremental encoder and magnetc switches or sensors.

The incremental encoder is situated either on the drive or in the shaft.

For cable elevators one prefers the encoder of the motor which could transfer on most of the inverters the Outputsignal at the controlunit.

In these case one inscribe at parameters F6 (rated speed), F7 (rated revolutionl) und F8 (solution of encoder) the real datas.

For slow running synchronous motors one has to play with parameter for rated speed, encoder pulses
eg $150 \mathrm{U} / \mathrm{min}$ at 2048 ppr becomes $600 \mathrm{U} / \mathrm{min}(* 4)$ und 512 ppr.

When the encoder is mounted in the shaft( circumferential cord) for the rated revolution speed a equivalent revolution speed has to be set.

In our used system with a carbon cord the values as follows come out

| (F7) | 0,8 | 1 | 1,2 | 1,4 | 1,6 | $\mathrm{~m} / \mathrm{s}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| (F8) | 294 | 367 | 441 | 514 | 588 | RPM |

## Manual - overview of system

## Re-levelling -sensor

Since then shaftcopying is made via the motorencoder the slip of the tractionsheave has to be compensated.

For this purpose there is a re-levelling plate in every floor from about 220 mm length This lenghtn isn't important but has to be identic in each floor.

This plate is evaluated from 2 inductive forksensorsCand D .
Cs above D is below

## Magnetic switch

Additionally there are in the head of the shaft and in the fosse two bistable magnetic switches( it could also be made with rollerswitches at the cabin)this for correction up and down and Inspection up and down.

Important that the switches are openers during a overrun they had to be open above and closed below. For the switches the same only reverse.

## Correction switches

The correction switches serve the deceleration at the terminal end stops in case of error (blackout of incremental encoder) and for learn trip. They are also used for correction of the incremental-encoder-datas. In the set of drawings, page 50 you can find these respectivly to the speed recommended distances. The exact pitch for the braking distance which is choosen by the controller is not important, as this is assigned by the chossen parameters. However, braking distance and pitch should not have a bigger difference than 45 cm

## Inspection endswitches

The lower inspectionswitch has to be mounted that he opens before the emergencyendswitch is actuated, but after the relevelling sensor D below the levelplate gets free. C is in the plate
for the upper inspectionendswitch it is correspondent means the IEO is avtive( contact opens)when the sensor C is above the levelplate and d is still inside the plate.

The emergency endswitchshould be a bit delocated so the elevator stops before the emergency endswitch is actuated.

The inspectionend-switches are important for the learning movement.

## Manual-overview of system

## Intelligent Magnetic sensors iMS45

Nowadays all above mentioned switches are integrated in one Sensorsystem. Those simplifies the the installation and adjustment considerably!

The iMS45 has up to four Magnetic sensors. Together with a programmable evaluation-electronic they could generate up to eight switch signals.

For a complete shaftcopying one iMS45-POS is sufficient .
Especially for elevators without engine room one has to ad one iMS45-SPD-Sensor.
For the monitoring of speed and sense of revolution.
Depicted on the drive monitor board, which is the depiction and evaluation unit.
The transfer is via an fail-safe RS485-connection.

## Design and function

## Design

The sensor is in a stable aluminium housing, which is also available as IP54-version which is used in firefighter lifts.The solenoids are flat solenoids with 15 mmx 7 mm of cross-section and a variable length. The solenoids are installed at the button of the arrester rails.

## Function

In the iMS45 are 4 solenoid sensors, which are mea uring the strengh and polarity of the magnetic field. An analysis unit detect the respective switching signals and send these serial to the cabine, respectively to the drive (driving wheel) for controlling/ stearing. Additionally the iMS45-POS have an independent transistor output for e.g. contacting a chanel of a security circuit.

## different detections:

* Single magnet north
* Single magnet south
* Doubble magnet upper north/ lower south
* Doubble magnet upper south/ lower north
* Tripple magnet north in the middle
* Tripple magnet south in the middle
* Crossing direction
* Crossing speed
* North/south transition is detected exactly of each milimeter, mostlikely independent on the distace

## Manual - overview of system

## Correct signal Inputs at AS.T030 (LEDs)

On the mainboard the signalinputs are depicted via LEDs. Those signal are transfered serial from the POS sensor to the drive monitor who directs the signals parallelto AS.T030 the sheme shows:
-elevator in the lowest leveling position within KU
-elevator in leveling position outside KU/KO
-elevator in highest leveling position within KO
elevator in the lowest leveling position within KU

| Input designation | X 4 | X 5 | X 6 | X 7 |  |  | X 18 | X 19 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| LED at AS.T030 | - |  |  | - |  |  |  |  |
| In control parametrised as | $*$ | $*$ | - | - |  |  | - | - |

elevator in leveling position outside $\mathrm{KU} / \mathrm{KO}$

| Input designation | X 4 | X 5 | X 6 | X 7 |  |  | X 18 | X 19 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

| LED at AS.T030 |  |  |  | - |  |  |  |  |
| In control parametrised as | $*$ | $*$ | $*$ | $*$ |  |  | - | - |

X18: correction up (Only relevant for short floor)
X19: correction down (Only relevant for short floor )
X4: correction up
X5:correction down
X6: Relevelling UP
X7: Relevelling DOWN
X18 (short north magnet) und X19 (short southmagnet) arm additional retardation switches and are only needed for short floor shorter than $1,6 \mathrm{~m}$ within the correction switches KU or KO. Normally they are not needed and they are not connected therefore.

The named signal has to be at AS.T029, otherwise a learning movement is not possible

## Manual-overview of system

## 7.AS380 Main board AS.T029

## Assignment of input/ Output:

The Inputs/ Outouts can be assigned -within defined limits-freely.
Sheme below shows how they are assigned in the very often cases. Individual signals could be assigned in special cases odifferent.

This will be underligned in the circuit sheme. Thus the circuit map is applicable!

AS.T029 connections:

## Manual-overview of system

## 12.Security Section

## Security circuit

The safety circuit always builded up in the same way and is devided into 3 sections for security switches:
Emergency stop contains all security switches, which are always activ, thus never are allowed to be by-passed. This affects all emergency stop switches, the counterweight switch, maintenace openings, etc.emergency control bypass contains all security switches, which get by-passed in return motion control,
thus safty gear, emergency-end-switch, speed restrictor.
doorzonenbypass contains all blocking switches of
the shaft doors and the door contacts of the
cabin doors.
At the end of the security circuit is the inspections- and return motion control.

## Optional security switch

In the connection scheme all popular security switches drawn in. Security switches which are not always necessary, like blocking switch of the B-door, are drawn in as optional. If it is availble it have to be marked on the connection scheme and certainly also connected.The terminals for optional security switches are factory-provided by-passed with wire-bridge. So it is secured, that the bridge get removed by connection of a switch

## Manual - overview of system

## Matter: By-passing of security-circuits

Basically it is not allowed to make security circuits effectless per by-passing. But it is not possible to install a lift without by-passing temporarily parts of the security circuits.
Only use wire-bridges for by-passing, which you install at the terminals for the security switches. With this handling in any case the bridge will be removed when you install the switch. Never use shorting plug bridges - you might forget these conventionally! As wire, please use an eye-catching one, but not the greenyellow colored one! Please also avoid to have these too long (they should not look out of the cabinet) - in worst case somebody is closing the door and you may have 230 V of the secuirity circuit at the cabinet

## Security circuit

The security circuit is only needed, if re-levelling with open or pre-operating doors is required! For hydraulic lifts is due to the re-levelling the security circuit mandantory! The assignment of the security circuit are two sensors, which are operating independent one from the other, to recognize where the door zones are, to compare the datas and respectivley make it possible to by-pass the door contacts within the door zones or not. For instance it should be attained the security of a castor security switch. The security circuit is based on the common principle of the strip circuit. Every circuit switch part have to change it's attitude in order to make an alliance possible

## Components

K10, K11 and K12 are contactor or security-relays with positively driven contacts. If a closer bonds, the opener stay open and contrarywise.

K10 allocated to the sensor B178 of door zone 1
K11 allocated to the sensor B179 of door zone 2
K12 monitoring of K10/B 178 and K11/B 179
K14 relay without security function, allows the controller the disconnection of the bridge
S50 security contact in inspection switch. By this is avoided that bypass occurs during inspection!

## Manual-overview of system

## Functionality

Initial position: Lift outside of the doorzone
K10 and K11 dropped-out, K12 tightened.
Lift runs in door zone: B178 and B179 get closed successive or simultaneous. First K10, than K11 activates. K12 drop-out after activation of K11.
by-pass
completed.
R12 and C12 delay the depression of K12 for max. 100 ms , in order to make
lock K11 possible.
Lift is leaving door zone: B178 and B179 opens, K10 and K11 depresses, K12 activate.

## Possible sources of error:

| Error | Simulation | Action during early opening door <br> door mopens in doorzone |
| :--- | :--- | :--- |
| B178 discontinued/K10not actuated | Pinch off X52.11 or B178 | No by-pass.Elevator stops in doorzone |
| B179 discontinued/K11not actuated | Pinch off X52.12 or B179 | No by-pass.Elevator stops in doorzone |
| B178 hot-äöwired/K10 not depressing | By-passing K178 <br> while leaving door <br> zone or bypas <br> between. X52.11 u. <br> X52.1 | While leaving door zone K11 is depressing. K12 not <br> actuates anymore.at the next run K11 is not actuation <br> anymore Lift make stop at the open door $\rightarrow$ <br> EMERGENCY STOP |
| B179 hot-wired/K11 not depressing | While leaving <br> doorzone -Bypassing <br> K179 or bypassing <br> between X52.12 u. <br> X52.1 | While leaving door zone K10 is depressing. K12 is <br> not actuating anymore. At the next run K10 is not <br> actuating anymoreLift make stop opening door $\rightarrow$ <br> EMERGENCY STOP |

According to EN81 14.1.1 one single error do not lead to a dangerous operating conditon and will be recognized, as the lift will make an emergency stop by disconnecting the security circuit while opening the door within a door zone. In addition there is existing a further monitoring done by the controller. Dependent up on the re-levelling sensors, which are independent from the door zone sensors, K14 is activated.

In the unlikely case, that both door-zone-sensors by leaving the door zone would be hot-wired, a by-pass outside of the door zone will be avoided by the circuit via K14.

## Additional Monitoring by control

The controller is monitoring via K10, K11, and K12 the security circuit. During the journey the contact chain have to be closed once inside the door zone and have to be opend once outside the door zone. In case of an error, the installation will be shut down at the next stop with error message. Part of encoder

## Scan control at the security circuit

On the board SM01 F5021 there are 4 inputs for 230 V . These are installed according to the requirements of EN81 at scan controls for security circuits. This is confirmed by TÜV with a confirmation assessment. Basically the circuit consist of pre-resistors, protection diodes and optocoupler with VDE-approbation.

## Manual - overview of system

It is executed the terms accourding to EN81 for a secure disconnection of the 230VAC-page from the 24VDC-page as well as for exclusion of errors

## $N$-wire

The N -wire of the security contactor , means motor contactor K 1 and K 2 , as well the brake contactor K8 and maybe K8 have to be controlled via the board! At a N-wire-breakage the contactor than have the necessity of drop-out, independent of the theoretical possible chance of a hot-wire in the optocouplers which may make a partial by-pass of the security circuit possible

## check

Connect the controller free of voltage! With the continuity checker between N -input terminal and A2 (N-terminal) of security contactor (K1, K2,K3, K8), check the run.With a pluged JP11(main board) you have a run, with pultruded JP11 there must not be any run..

## Pilot relay

On the board SM01sup (F5021) there are also 4 pilot relays for security contactors . This part of circuit is also confirmation checked, means it is possible to connect directly the end of the security circle, the security contactore sources their controller voltage directly out of the security circle.
The security contactors, motor contactors K 1 and K 2 , as well the brake contactor K8 are seperatly monitored. If there is one of the contactors is not depressed before a journey, the control get s blocked and have tho be reseted manually

## Monitoring of run

SmartCom F5021 is monitoring via the encoder of the engine and the re-levelling-sensors the reactions of the lift in regards on the driving commands to the inverter. If there are signals missing, the drive get's shutdown, latest after 20 sec . .Restart of journey only possible after reset of the main board.

## CHECK

1. Advise the lift to drive from the lowest to the topmost stop and do the unplug JP7 respectively JP8 (Encoderinputs) at the main board. The lift have to be shut dwon after arround 20 sec.
2. Uninstall 170 or 171 (re-levelling-sensors). After arround 20sec. re-levelling the lift get shut dwon. You easily can set diving commands via the status window "Call.Func".For short lifts 20sec. may be a long time frame. In this case you could reduce temporarily the parameter"Monitoring of journey" via the menu "parametergroup F" in order to simplify the checking

## Manual-overview of system

## 13.Advice of acceptance test

Lift controller of STEP Sigriner Elektronik GmbH are manufactured and checked with EN81 and VDEstandards. The used components, especially the main- and auxiliary contactors are selected respectively to the requirements of EN81, VDE0100, VDE0660.
All adjustable components, like engine-security-switch,frequency inverter etc. are allready pre-adjusted by us as far as possible. It is incumbent upon the installing company to adjust these components before implementation with respect to the resources..

By default the security cycle is fused with a power protection switch withF2 (2A Charakteristik C).
As amaximum a power protection switch with 4A can be used.

## Generally

Keep doors closed: $\quad$ To check troublefree the doors could be blocked withF165 bit1=1

Inspection run: has always priority before return motion and it is also possible with activated return motion control. The by-pass of the security switch is deactivated. With F76 and F77 virtuell inspection-end-switches could be set. This to avoid that accidently the fold support in the fosse are overrunned. As soon as the shaft copying isn't completly engaged set bith values on „,0". within the doorzone with AUF/ Zu button the function of the doors could be checked. Otherwise during inspection run doors are always closed.

Return motion run: this is only possible with deactivated inspection control. Appropriate security switches, like emergency-end-switch, arrester-switch etc. will be by-passed. The return motion is also stopped by the virtual inspection end switches F76/77.

Cabin light: If failure of cabin light ( simulation F02) the lift stops at next floor and door opens.

Motor temperature A PTC switch-OFF leads as well to a shut down at the next possible stop.

## Isolation measurement:

By default the controller undergo a isolation masurement in the factory. The IN-SITU arranged measurement refers only to the connected ressources of the lift

Please respect imperativly the safety regulations while executing this procedures. There is danger for limb and life :

In order to avoid damages of the controller, switch off the respective fuse F2 at the controller for measurements. Connection of frequency inverter, USV-systems and other systems with power semiconductors and filter, most likely have to be disconnected or hot-wired according to manufacturers for testing purpose. For this follow the advises of the manufactures.

## Manual - overview of system

## Inccorect done isolation measurement can provoque extensive danger. STEP-Sigriner Elektronik GmbH is not liable for any damage!

Mainly applies:

- Remove the yellow-green bridge circuit between mass (200) and ground (PE)
- check wether mass is now free of ground -with ohmmeter
- inverters, door control facilities disconnect if applicable.
- Is there still connection between mass and ground while bridge ( 200 to GND) is disconnected, please check door control devices, light grids, and load detectors. Those devices often has internal internal ground connections and had to be isolated.
- Now an isolation measurement could be executed riskless, as far as it is always measured aginst ground.

## Check of run-time monitoring:

In normal mode in menu Commission>Test Menu>Drive T. Test activate. The parameter for the run-time is now temporarily reduced to 2 sec . and a command is send. The elevator starts and should make after 2 sec an emergency stop.

## End switch movement:

First set F79 Bit 1 to allow an overrun over the virtual end-switches.
Send elevator in normal mode into uppermost and lowermost floors.
For this activate in menu Commissioning>Test Menu> Up Limit Test or Dn Limit .
The elevator runs now up or down until security loop is opened.
The distance from the levelposition is displayed.
With return-motion control the elevator could be moved over the end switches to test his traction.
F79 Bit1 wieder auf 0 setzen.

## Effectiveness of the brakes (one-sided brake)

Switch in normal mode the power supply to USV ( Service-Panel).
Send elevator from lowermost floor up (via call). When nominal speed is reached push one of the brakebuttons and hold. Elevator makes emergency Stop, even one brake is disengeged via the button, though elevator has to stop.

Test the same with the other brake.

## Contactor monitoring:

Change with parameter F25 temporarily the Input orientation (NC/NO) for X8 (contactor Motor) and then X9 (contactor Brake) . control has to detect latest at next move an error and give out error message.

## Brake monitoring switch:

Check switches of brake monitoring either through displug or temporarily change of input orientation from X10 und X11 in parameter F25 .

## Manual-overview of system

## Measurements in security circuit

The security circuit is monitored via a residual current circuit breaker and a 2 A or 4 a fuse.
The measurement of the loop resistance through the RCI is not possible or doesn't make sense. Because of the leak current of 30 mA is the loop resistance is this benign. It is crucial that the RCI disconnect above 30 mA if the test is made from any point against ground.,

This could be made with a test device or an adapted DUSPOL
Due to the desigh of the elevator the security circuit is not easy to acced. Thats way important measurepoints are brought to the service panel via X88 .
On sheet 3 on circuit diagramm you find important advices.

## Triangle monitoring „DKU"

## Backround

This device has to perform following task. As soon as somebody wants to enter the cabin and opens the shaft door with the triangle key the elevator has to stop.

So it is prevented that somebody is hurt, if he entered the shaft without stopping the elevator by the emergency stop.If he had entered and the door is closing behind him giving free the elevator.

When there is a short fosse or short head the DKU is a temporarily tool to errect the fold support or brakets.
Furthermore by using the DKU the housing of counterweight is not neccessary and it is taken in account the inspection control conform the EN81-20

## Functional principle

Generally the DKU consists of a relay circuit in lock (maintained command) via the monitor switches of the triangle lock-release.

The monitor switches ares in a normal open configuration.and arranged in a serial circuit.. so as soon as one triangle is opened the relais depress and the circuit is open.

For a short fosse, missing hausing of counterweight or missing Inspection control one contact in the shaft door is enough. When head of shaft is shortened, every shaft door has to have a contact!

The power supply of DKU has to be battery backed- this to prevent a triggering when power failure.

## Functional check

The elevator is in normal mode and ready .

## Manual - overview of system

## Checking of effectiveness from „DKU"

Unlock one of the monitored doors. Opening the door is not neccessary.
Now the elevator should not move neither by call or return-run button.
After apply of SSR at service Panel the elevator should move.
Repeat this check for every door under surveillance of DKU.

## Simulation of ,,sticking" Reset button

Hold the SSR pushed. The elevator should not move in normal mode or return move.
After release the elevator should move .

## Check of the Inspection control

Attention Imperatively respect the following:
Allways set emergencvy stop before entering shaft or cabinceiling. This avoids accidents if test comes out negativ.

Move the elevator with return move in one floor so that you could enter the cabintop.
If applicable erect the fold support in the fosse into protect position.
Now the elevator should move with the inspection control on the top or in the fosse.
Shut down the inspection, leave the fosse and keep the fold support in position.

## Check Reset only possible with nonactive folded support

Try to reset DKU when door is closed.. this shouldn't be possible, means elevator cannot move not in normal mode or return move.

When there is no shortened fosse the reset could be made when closing all shaft doors. Put now back the fold support in normal mode position. Protected area deactivated.. Leave the fosse and close shaft door(s).

## final check

the elevator should not move-not in normal mode nor in return mode.
Actuate SSR. Now the elevator should move..

## Manual-overview of system

## Instruction for A3 check

## General

## application of the instruction

these instruction completes the general Control manual at the matter A3 protection for accidental movement(UCM).

Please notic also the advices in the manual for the control AS380.
The system bases on the security circuit SM011B, which is for the bypass of the door contacts for relevelling with open door or preopening door and for detection of uncontrolled leave of the doorzone and for the shut down of the motorbrake.

## security

to assume that:

- the elevator facility is installed accordingly the regulations of the manufacturer and ready for operation
- The facility has a service braking device or an additional brake which can be used as a A3 brake and can be piloted from the security circuit.
- Alle Persons which are consigned with the installation, and checking of the facility has the required knowledge and skills also especially regarding the electrical and mechanical hazards from elevators.
- to remind: In a elevator facility are hazards by electrical strokes, via the mecanic (crushing, cropping) etc and furthermore hazards through the design drop, fall etc.
- Important: do not only think at you, but on people which could be in the danger zone!
- During the execution of tests think also on the possibiliy of failure. Thats way at no time somebody should stay in the danger zone.

## Functional principle

## Introduction:

When the cabin is leaving the doorzone the security loop is opening when cabin door opens and the brake at the end of the security circuit connected actuates. By this the cabin is braking down.

This brake could be an approved A3service brake or an additional brake.
Through a good design of the lenght of the doorzone and the brake characteristic should be ashured that the braking distance goes below the required braking distance.

This is made by calculation and the practical test on each facility.
The detection of an uncontrolled movement is independant from the control.

## General function check:

The UCM-Function is tested with closed door in a levelled position.
To check this function the K14 is to actuate. This close the bridge from the door. Simultanely the part of the doorcontacts is opened via a testrelay (K.A3T) to simulate an open door.

## Manual - overview of system

The doors stay closed to avoid hazard if the test fails.

## Functional check-Version A with trundle (via check menu):

These procedure is only designated for cable elevator with gearless drives.( synchronous motors) and simulates the case of a noncontrolled trundle.

The paces for checking of UCM Function are integrated in the software of the AS380 control means the test-relay K.A3T and K14 is directly triggered.

- Elevator is ready for operation in a middle floor.
- Doors are closed.
- Now activate in the menu Test the UCM Test A
- via the Testrelay K.A3T the door circuit is opened to check when door is closed. K14 is avtivated to close the bridging.
- Now K2 (Motorcontactor) and K8 (Brakecontactor) is actuated.
- The elevator trundles up ( cabin empty) or down ( cabin loaded).
- After leaving the doorzone the elevator has to stop!
- The elevator has to come to a stop within the limit values.
- The passed distance is indicated on the display or can be measured after the opening from the shaftdoor.
- If the elevator trundles away more than 2 m the test has to be aborted.

## Functional-check Version B with inverter (via check-menu):

these procedure is designated for cable elevator with gear drives.( asynchronous motors) and simulates the movement with defined acceleration (caused by the inverter)

The paces for checking of UCM Function are integrated in the software of the AS380 control means the test-relay K.A3T and K14 is directly triggered.

- Elevator is ready for operation in a middle floor.
- Doors are closed.
- Now activate in the menu Test the UCM Test B
- via the Testrelay K.A3T the door circuit is opened to check when door is closed. K14 is avtivated to close the bridging.
- Now a normal run Up ( empty cabin) or down (loaded cabin) acuated.
- After leaving the doorzone the elevator has to stop!.
- The elevator has to come to a stop within the limit values.
- The passed distance is indicated on the display or can be measured after the opening from the shaftdoor.
- If the elevator trundles away more than 2 m the test has to be aborted.
- With the below shown calculations the maximal breaking distances can be calculated. Basis is the set acceleration.

## Manual-overview of system

- The measured braking distance should be considerably below the calculated one!
- By calculating the braking distance for the worst case can be established.This has to be below the permissible limits.

## Example: Calculation of the braking distance

input values:
Max. average acceleration: $\mathrm{a}=2500 \mathrm{~mm} / \mathrm{s}^{2}$ (z.B. max. possible acceleration)
lenghts of doorzone $\mathrm{Xa}=110 \mathrm{~mm} \quad \rightarrow$ lenghts of magnet $150 \mathrm{~mm}-40 \mathrm{~mm}$

Response time system SM011B inkl. Cont. $\mathrm{Te}=40 \mathrm{~ms} \quad \boldsymbol{\mathrm { C }} 9 \mathrm{~ms}+30 \mathrm{~ms}$ contactor
Response time Brake $\mathrm{Tb}=200 \mathrm{~ms}$
$\rightarrow$ dependant of the used brake
average deceleration $=2000 \mathrm{~mm} / \mathrm{s} 2$
$\rightarrow$ dependant of the used brake
calculation of time until doorzone is left (detection time-leaving doorzone)
$\mathrm{Tt}=\sqrt{\frac{2 * X a}{a}}=\sqrt{\frac{2 * 110 \mathrm{~mm}}{2500 \mathrm{~mm} / s^{2}}}$
$\mathrm{Tt}=0,3 \mathrm{~s}$
calculation og ther total response time $\operatorname{Tr}$ (detection+electronic+brake)
$\mathrm{Tr}=\mathrm{Tt}+\mathrm{Te}+\mathrm{Tb}$
$\mathrm{Tr}=0,3 \mathrm{~s}+0,04 \mathrm{~s}+0,2 \mathrm{~s}=0,54 \mathrm{~s}$
calculation of covered distance Xb during total response time Tr :
$\mathrm{Xb}=0,5 * \mathrm{a} * \mathrm{Tr}^{2}=0,5 * 2500 \mathrm{~mm} / \mathrm{s}^{2} *(0,54 \mathrm{~s})^{2}=364,5 \mathrm{~mm}$
calculation of the max. acomplished speed Vmax:
$\mathrm{Vmax}=\mathrm{a} * \mathrm{Tr}=2500 \mathrm{~mm} / \mathrm{s}^{2} * 0,54 \mathrm{~s}=1350 \mathrm{~mm} / \mathrm{s}$
calculation of the stoppimng distance Xd :
$X d=X b+\frac{V m a x^{2}}{2 * a b}=364,5 \mathrm{~mm}+\frac{(1350 \mathrm{~mm} / \mathrm{s})^{2}}{2 * 2000 \mathrm{~mm} / \mathrm{s}^{2}}=820,2 \mathrm{~mm}$

A3 would be met for this example.
